

# Biofortify African local food crops with iron and zinc using agroecological practices – choice of organic residual products to fertilize the crops

## INTRODUCTION

- Almost half of Africa's population suffers from iron and zinc malnutrition (Ritchie, 2017)
- Iron and zinc deficiencies are among the leading causes of diseases in Africa (WHO, 2002)
- Food products of *ca.* 48% of Africa's population lack essential nutrients such as iron and zinc (Wawa, 2019)
- Agro-biofortification is described by WHO (2019) as an effective process for improving the nutritional quality of food products
- Application of organic residual products rich in iron and zinc, combined with local efficient microorganisms, in a production system, is one way of agro-biofortification

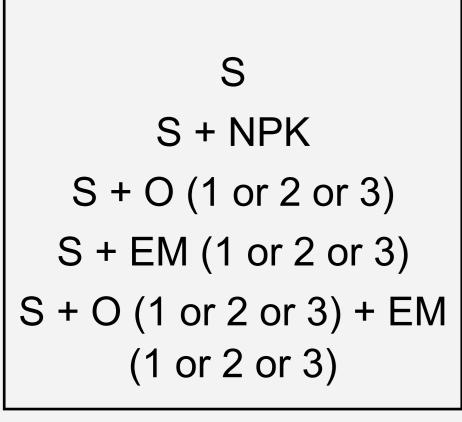

## OBJECTIVE

Select two combinations of organic residual products (O) collected in Senegal, and local efficient microorga-

nisms (EM) according to their quantities of iron and zinc released

# **MATERIALS AND METHODS**

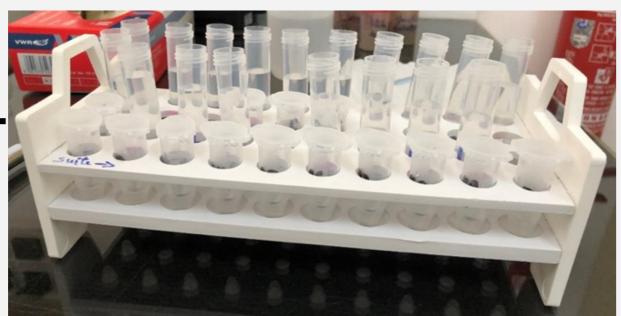

Evaluation of quantities of iron and zinc released in different combinations was carried out using diffusive gradient in thin films (DGT) technique, after mineralization during 0, 7, 14 and 28 days

Combinations

DGT deployment on different combinations after 0, 7, 14 and 28 days mineralization at 28 °C

Dilution of 1 ml of elution solution in 7 ml of demineralized water

Determination of iron and zinc released content using ICP-MS

S = soil; O1 = cow dung; O2 = poultry droppings; O3 = sewage sludge; EM1 = Saint Louis (peanut + millet); EM2 = south groundnut basin (peanut); EM3 = south groundnut basin (rice); ICP-MS = Inductively coupled plasma mass spectrometry

E. Noumsi Foamouhoue<sup>\*1</sup>, S. Legros<sup>1</sup>, P. Fernandes<sup>1</sup>, H. Founoune Mboup<sup>2</sup>, J.-M. Médoc<sup>1</sup> <sup>1</sup>CIRAD, Senegal; <sup>2</sup>ISRA, Senegal

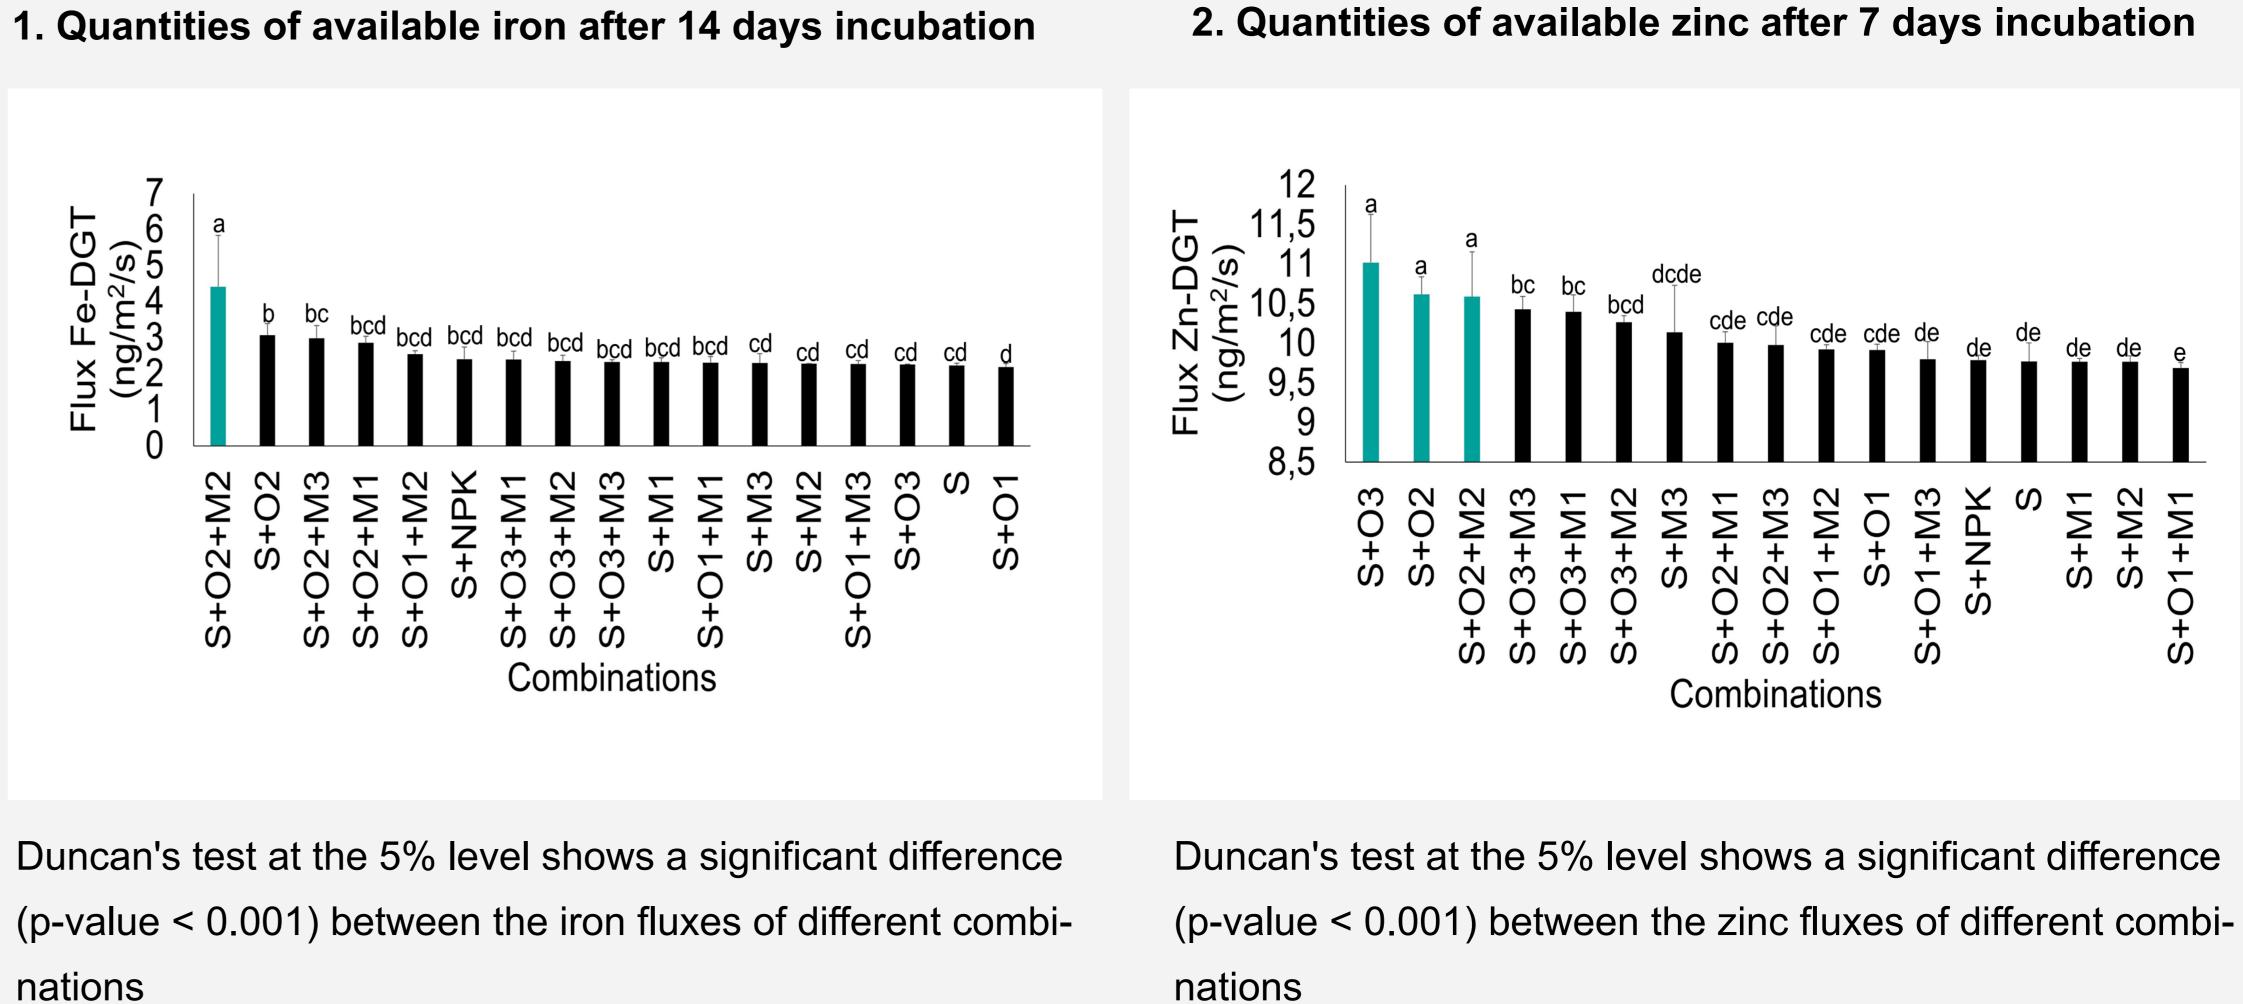

Recuperation of DGT after 24 hrs incubation at 28 °C

Extraction of resin binding gel from DGT

Elution of resin binding gel in HNO<sub>3</sub> 1M for 24 hrs

nations

tions have the highest quantity of zinc released

ducts and local efficient microorganisms tested for further field trials

Poultry manure and sewage sludge in combination with EM from south groundnut basin (peanut) will be tested under experimental field conditions considering also local agricultural practices, to evaluate the Fe and Zn gain of the grain of cowpea and millet

4<sup>th</sup> International Conference on GLOBAL FOOD SECURITY 2020

RESULTS

# CONCLUSION

1.Soil + poultry droppings + EM south groundnut basin (peanut) combination has the highest quantity of iron released

2. Soil + sewage sludge, soil + poultry droppings and soil + poultry droppings + EM south groundnut basin (peanut) combina-

3. Poultry droppings, sewage sludge and south groundnut basin (peanut) were selected among organic residual pro-
